1 Propositional Logic and Boolean Algebras

1.1 Preliminaries

Definition 1. A *Boolean algebra* is a tuple $(\mathbf{B}, \wedge, \vee, \neg, 0, 1)$ of a set \mathbf{B} with operations \wedge, \vee, \neg and elements $0, 1 \in \mathbf{B}$ such that the following axioms hold for all $a, b, c \in \mathbf{B}$:

- both \wedge and \vee are associative and commutative;
- $a \vee (a \wedge b) = a$, and $a \wedge (a \vee b) = a$;
- 0 is the identity of \vee , and 1 is the identity of \wedge ;
- \vee distributes over \wedge and vice versa;
- $a \vee \neg a = 1$, and $a \wedge \neg a = 0$.

Let $a, b \in \mathbf{B}$ be arbitrary. Let \leq be a partial order on \mathbf{B} defined by $a \leq b$ if $a = b \wedge a$ (or, equivalently, $a \vee b = b$), and let $a < b$ denote $a \leq b$ and $a \neq b$.

Definition 2 ([5]). An element $a \neq 0$ of a Boolean algebra \mathbf{B} is an *atom* if there is no $x \in \mathbf{B}$ such that $0 < x < a$. A Boolean algebra is *atomic* if for every $a \in \mathbf{B} \setminus \{0\}$, there is an atom x such that $x \leq a$.

Lemma 1 ([2]). For any two distinct atoms a, b in a Boolean algebra, $a \wedge b = 0$.

Lemma 2 ([3]). All finite Boolean algebras are atomic.

Theorem 1 ([2]). Let \mathbf{B} be a finite Boolean algebra. Then every $a \in \mathbf{B} \setminus \{0\}$ can be uniquely expressed as $a = \bigvee_{i \in I} m_i$ for some set of atoms $\{m_i\}_{i \in I}$.

Definition 3 ([1]). A (strictly positive) *measure* on a Boolean algebra \mathbf{B} is a function $m : \mathbf{B} \rightarrow [0, 1]$ such that:

1. $m(1) = 1$, and $m(x) > 0$ for $x \neq 0$;
2. $m(x \vee y) = m(x) + m(y)$ for all $x, y \in \mathbf{B}$ whenever $x \wedge y = 0$.

1.2 New Results

Definition 4. Let \mathbf{B} be a finite Boolean algebra, let L be a subset of \mathbf{B} such that every atom m can be uniquely expressed as $m = \bigwedge_{i \in I} l_i$ for some $\{l_i\}_{i \in I} \subseteq L$, and let $w : L \rightarrow \mathbb{R}_{>0}$ be arbitrary. The *weighted model count* $\text{WMC} : \mathbf{B} \rightarrow \mathbb{R}_{\geq 0}$ is defined as

$$\text{WMC}(a) = \begin{cases} 0 & \text{if } a = 0 \\ \prod_{i \in I} w(l_i) & \text{if } M \ni a = \bigwedge_{i \in I} l_i \\ \sum_{i \in I} \text{WMC}(m_i) & \text{if } \mathbf{B} \setminus (M \cup \{0\}) \ni a = \bigvee_{i \in I} m_i \end{cases}$$

for any $a \in \mathbf{B}$. Furthermore, we define the *normalised weighted model count* $\text{nWMC} : \mathbf{B} \rightarrow [0, 1]$ as $\text{nWMC}(a) = \frac{\text{WMC}(a)}{\text{WMC}(1)}$ for all $a \in \mathbf{B}$.

Proposition 1. *nWMC is a measure for any finite Boolean algebra \mathbf{B} .*

Proof. First, note that Property 1 of Definition 3 is satisfied by the definition of nWMC . Next, in order to prove Property 2, let $x, y \in \mathbf{B}$ be such that $x \wedge y = 0$. We want to show that

$$\text{nWMC}(x \vee y) = \text{nWMC}(x) + \text{nWMC}(y)$$

which is equivalent to

$$\text{WMC}(x \vee y) = \text{WMC}(x) + \text{WMC}(y). \quad (1)$$

If, say, $x = 0$, then Eq. (1) becomes

$$\text{WMC}(y) = \text{WMC}(0) + \text{WMC}(y) = \text{WMC}(y)$$

(and likewise for $y = 0$). Thus we can assume that $x \neq 0 \neq y$ and use Theorem 1 to write

$$x = \bigvee_{i \in I} x_i \quad \text{and} \quad y = \bigvee_{j \in J} y_j$$

for some sequences of atoms $(x_i)_{i \in I}$ and $(y_j)_{j \in J}$. If $x_{i'} = y_{j'}$ for some $i' \in I$ and $j' \in J$, then

$$x \wedge y = \bigvee_{i \in I} \bigvee_{j \in J} x_i \wedge y_j = x_{i'} \wedge y_{j'} \neq 0,$$

contradicting the assumption. This is enough to show that

$$\begin{aligned} \text{WMC}(x \vee y) &= \text{WMC} \left(\left(\bigvee_{i \in I} x_i \right) \vee \left(\bigvee_{j \in J} y_j \right) \right) = \sum_{i \in I} \text{WMC}(x_i) + \sum_{j \in J} \text{WMC}(y_j) \\ &= \text{WMC}(x) + \text{WMC}(y), \end{aligned}$$

finishing the proof. □

2 First-Order Logic and Polyadic Algebras

2.1 Preliminaries

What follows is a summary of [4].

Let \mathbf{B} be a Boolean algebra (of propositions). Let X be the (non-empty) domain of discourse. Let I be an index set, elements of which can be interpreted as variables. The elements of X^I are functions from I to X . For any $x \in X^I$ and $i \in I$, we write x_i to represent $x(i) \in X$. Let \mathbf{A}^* be the set of all functions $X^I \rightarrow \mathbf{B}$, and note that it forms a Boolean algebra with operations defined pointwise.

Let T be the semigroup of all $I \rightarrow I$ transformations. For any $\tau \in T$, let $\tau_* : X^I \rightarrow X^I$ be defined by

$$(\tau_* x)_i = x_{\tau i}$$

for all $x \in X^I$ and $i \in I$. We can then define \mathbf{S} to be a map from T to Boolean endomorphisms of \mathbf{A}^* defined by

$$\mathbf{S}(\tau)p(x) = p(\tau_* x)$$

for all $x \in X^I$ and $p \in \mathbf{A}^*$.

For any $J \subseteq I$, let J_* be the relation on X_I defined by

$$xJ_*y \iff x_i = y_i \text{ for all } i \in I \setminus J$$

for all $x, y \in X^I$. For any $J \subseteq I$, we then define $\exists(J)$ to be a transformation $\mathbf{A}^* \rightarrow \mathbf{A}^*$ defined by

$$\exists(J)p(x) = \bigvee_{\substack{y \in X^I, \\ xJ_*y}} p(y)$$

for all $p \in \mathbf{A}^*$, provided this supremum exists for all $x \in X^I$.

Finally, a *functional polyadic (Boolean) algebra*² is a subalgebra \mathbf{A} of \mathbf{A}^* such that:

- $\mathbf{S}(\tau)p \in \mathbf{A}$ for all $p \in \mathbf{A}$ and $\tau \in T$;
- $\exists(J)p \in \mathbf{A}$ for all $p \in \mathbf{A}$ and $J \subseteq I$.

Definition 5. Similarly to \exists , a *constant* c is a mapping from $\mathcal{P}(I)$ to Boolean endomorphisms of \mathbf{A} such that:

- $c(\emptyset) = \text{id}_{\mathbf{A}}$;
- $c(J \cup K) = c(J)c(K)$;
- $c(J)\exists(K) = \exists(K)c(J \setminus K)$;
- $\exists(J)c(K) = c(K)\exists(J \setminus K)$;
- $c(J)\mathbf{S}(\tau) = \mathbf{S}(\tau)c(\tau^{-1}J)$

for all $J, K \in \mathcal{P}(I)$ and $\tau \in T$. If J is a singleton set $\{i\}$, we will simply write $c(i)$ instead of $c(J)$.

2.2 New Results

Proposition 2. Let \mathbf{B} be a finite Boolean algebra with a measure $m : \mathbf{B} \rightarrow [0, 1]$. Let \mathbf{A} be a \mathbf{B} -valued functional polyadic algebra with domain X and variables I . For any $p \in \mathbf{A}$, let $\text{sup}(p) = \bigvee_{x \in X^I} p(x)$. Let $m^* : \mathbf{A} \rightarrow [0, 1]$ be defined by

$$m^*(p) = \sum_{\substack{\text{atom } y \in \mathbf{B}: \\ y \leq \text{sup}(p)}} m(y)$$

for all $p \in \mathbf{A}$. Then m^* is a measure on \mathbf{A} .

Remark. While defining m^* as $m^*(p) = m(\text{sup}(p))$ might look tempting, this definition is not additive.

Proof. First, since $1 \in \mathbf{A}$ is a function $1 : X^I \rightarrow \mathbf{B}$ defined as $1(x) = 1$, we have that $m^*(1) = m(1) = 1$. If $m^*(p) = 0$ for some $p \in \mathbf{A}$, then it must be the case that

$$\bigvee_{x \in X^I} p(x) = 0$$

which means that for all $x \in X^I$, $p(x) = 0$, which is equivalent to saying that $p = 0$. Thus, $m^*(p) > 0$ for $p \in \mathbf{A} \setminus \{0\}$. □

¹The universal quantifier $\forall(J)$ is then defined as $\forall(J)p = \neg(\exists(J)\neg p)$ for all $p \in \mathbf{A}^*$.

²To be more explicit, a \mathbf{B} -valued functional polyadic algebra with domain X and variables I .
